## Overarching Goal

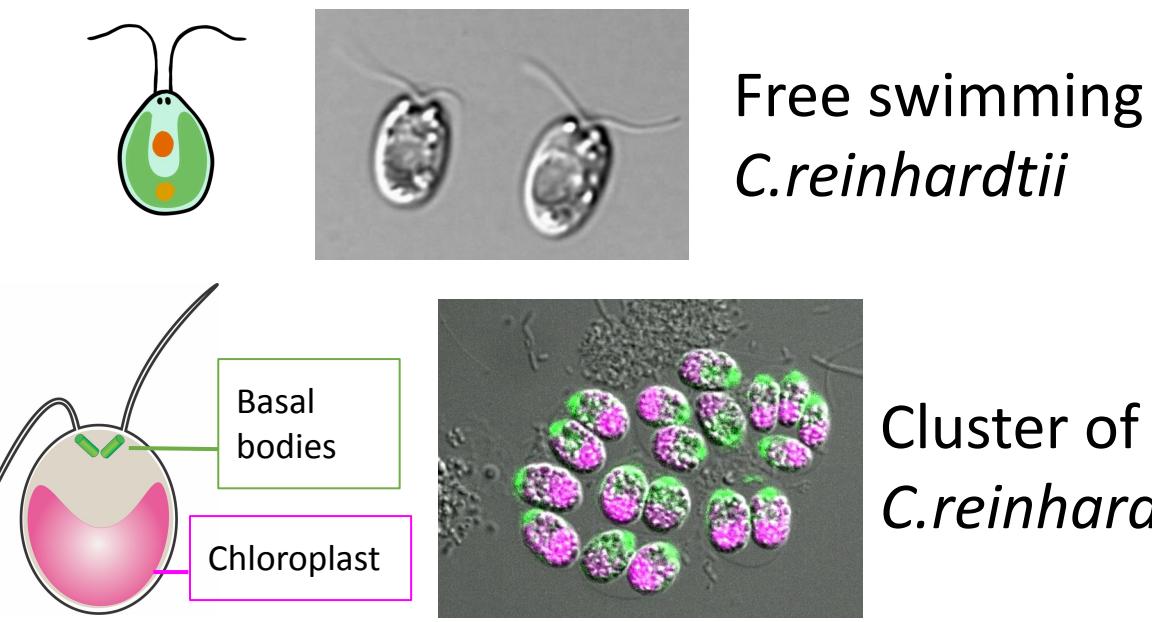

We bridge **cell biology**, **evolutionary ecology**, and **math** to study the effects of warming effects on microbial food webs.

1. Food web complexity?
2. Standing genetic variation?
3. Temperature?
4. What genes?

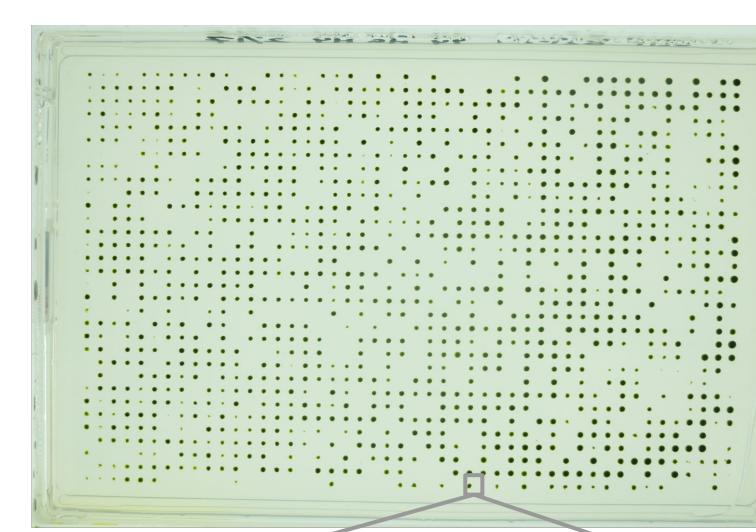

## Model System

### Algal Prey: *Chlamydomonas reinhardtii*

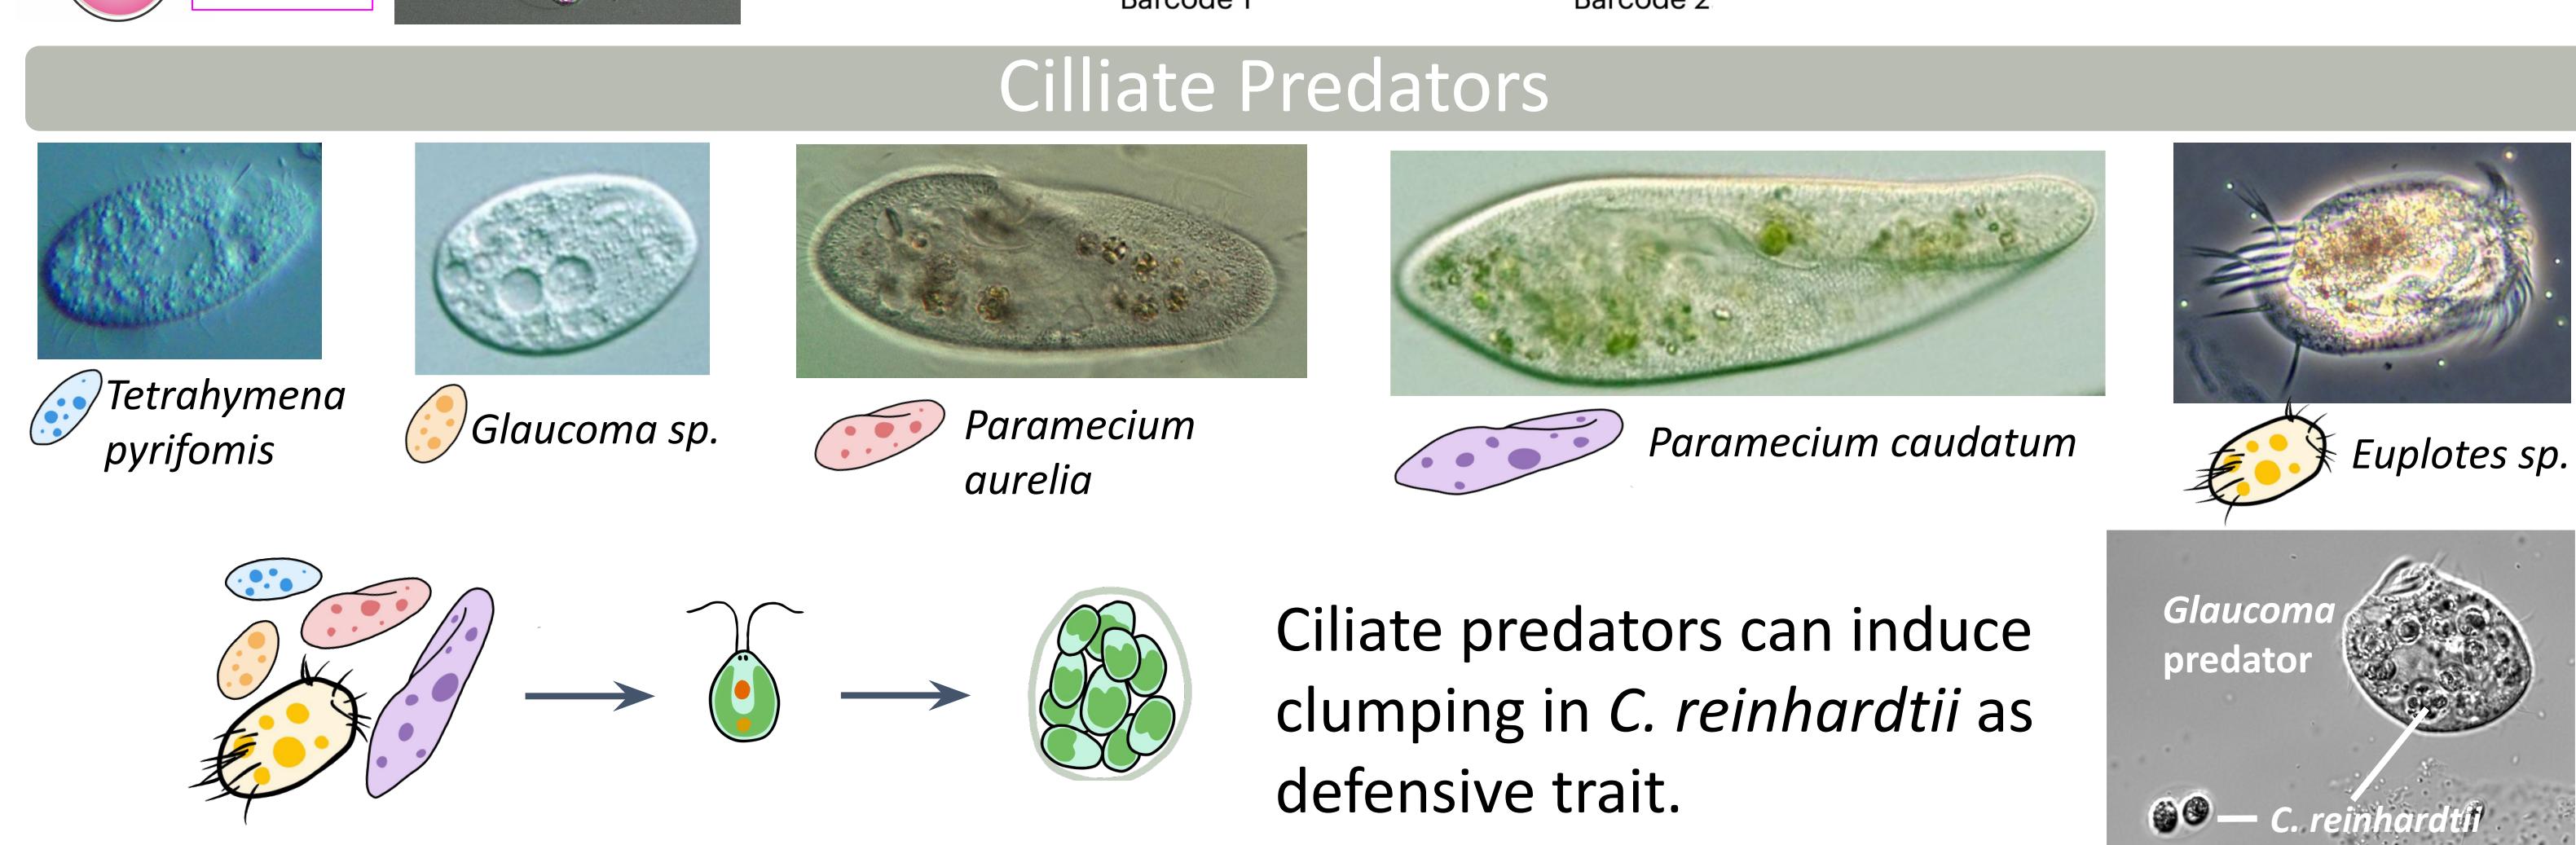

*C. reinhardtii* is a unicellular green alga that exhibits two forms in its division cycle:

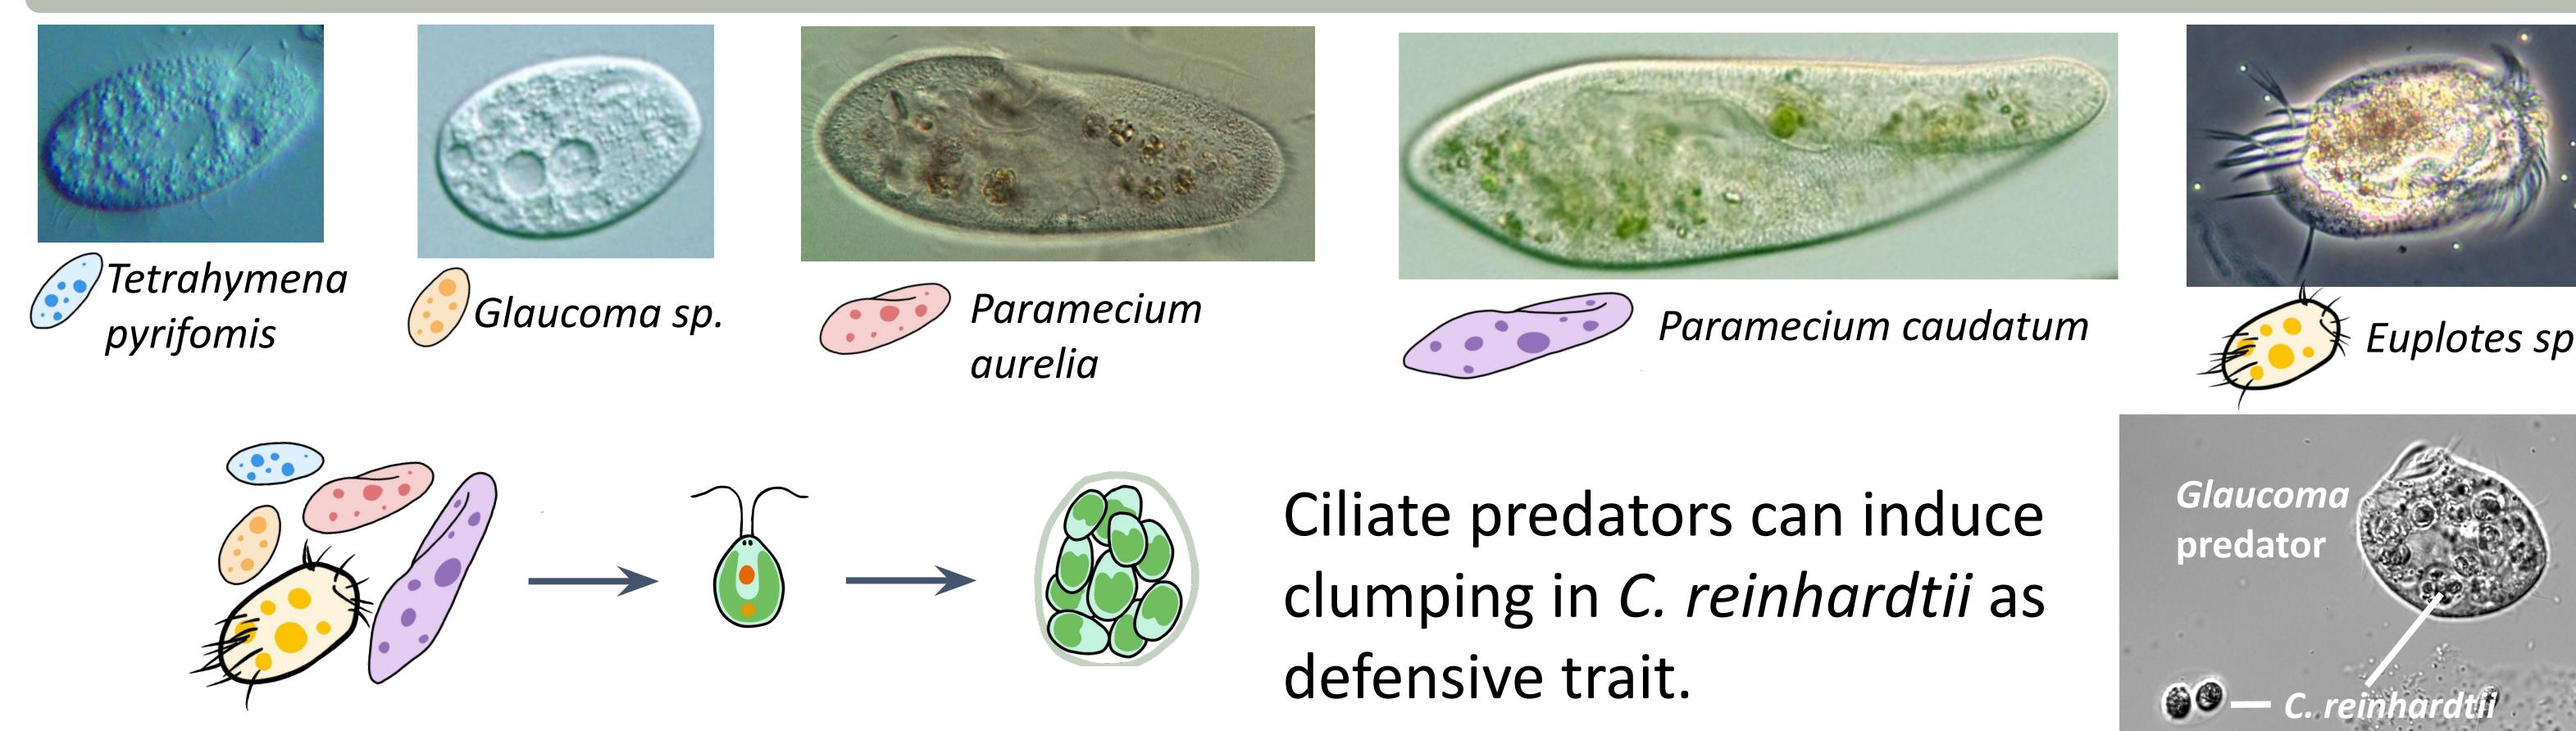

### CLiP Mutant Library

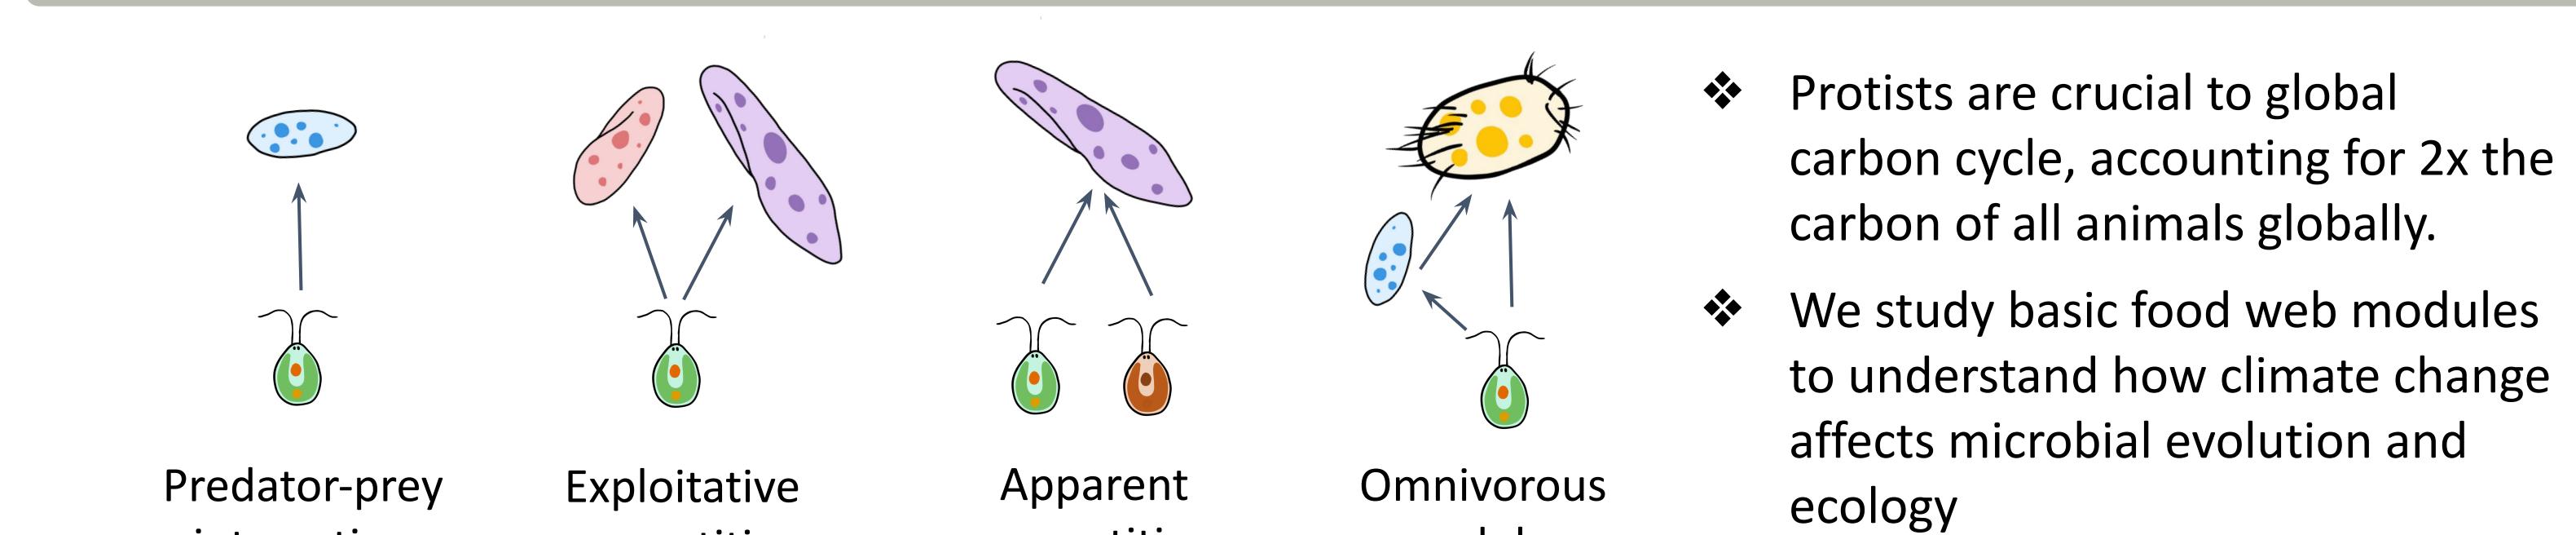

- ❖ 13,000 knock-out mutant strains
- ❖ Unique DNA barcodes for each strain
- ❖ Allows phenotype to genotype mapping

### Ciliate Predators

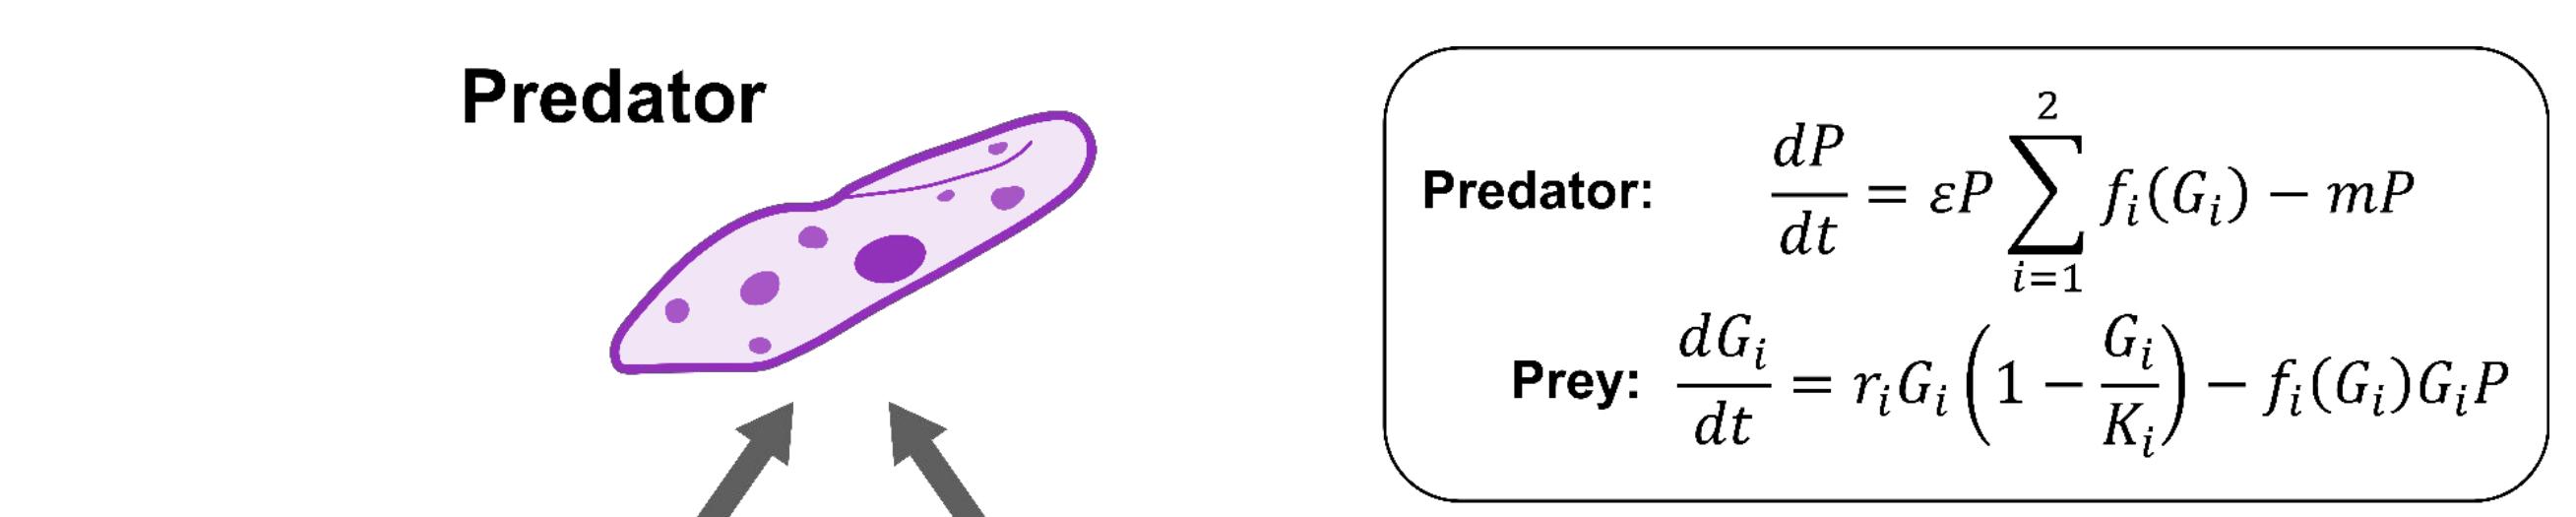

### Microbial Food Web

### Team Members

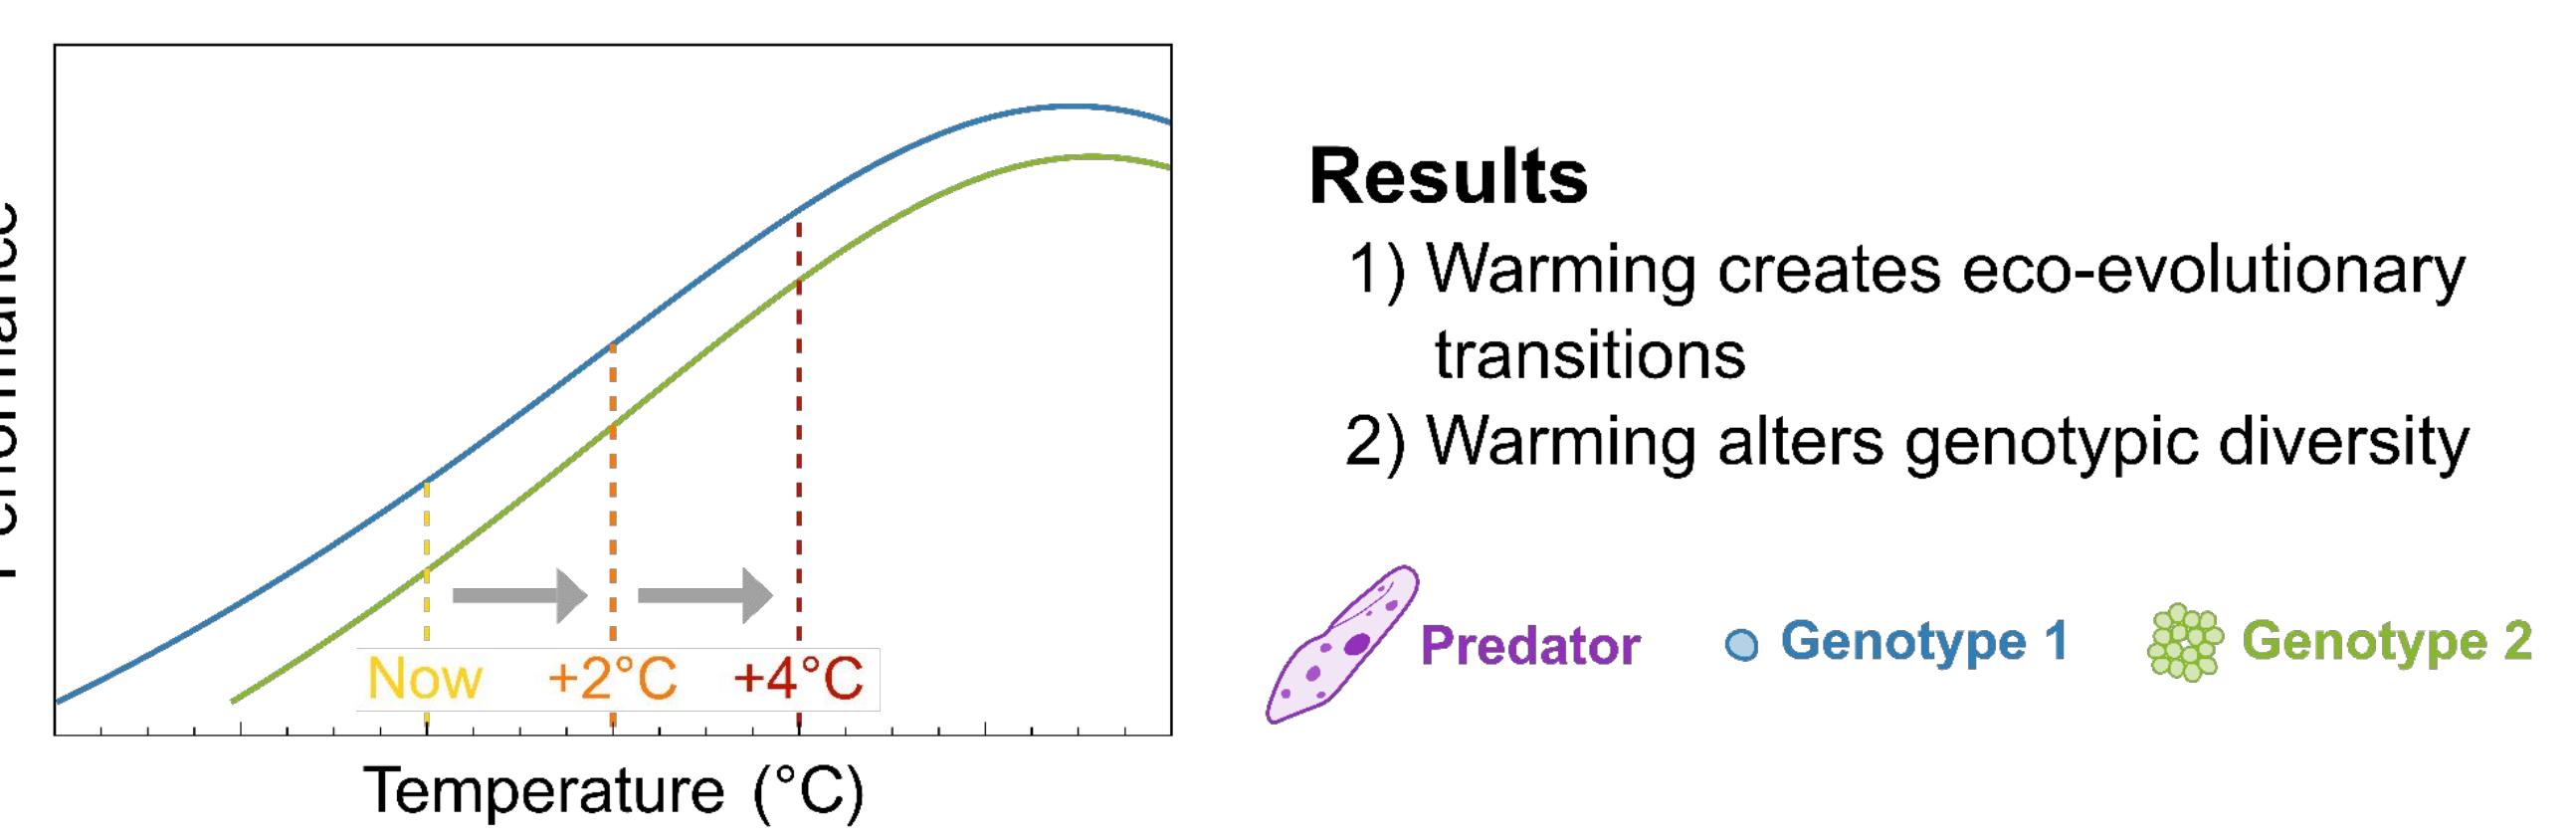

## Mathematical Modeling

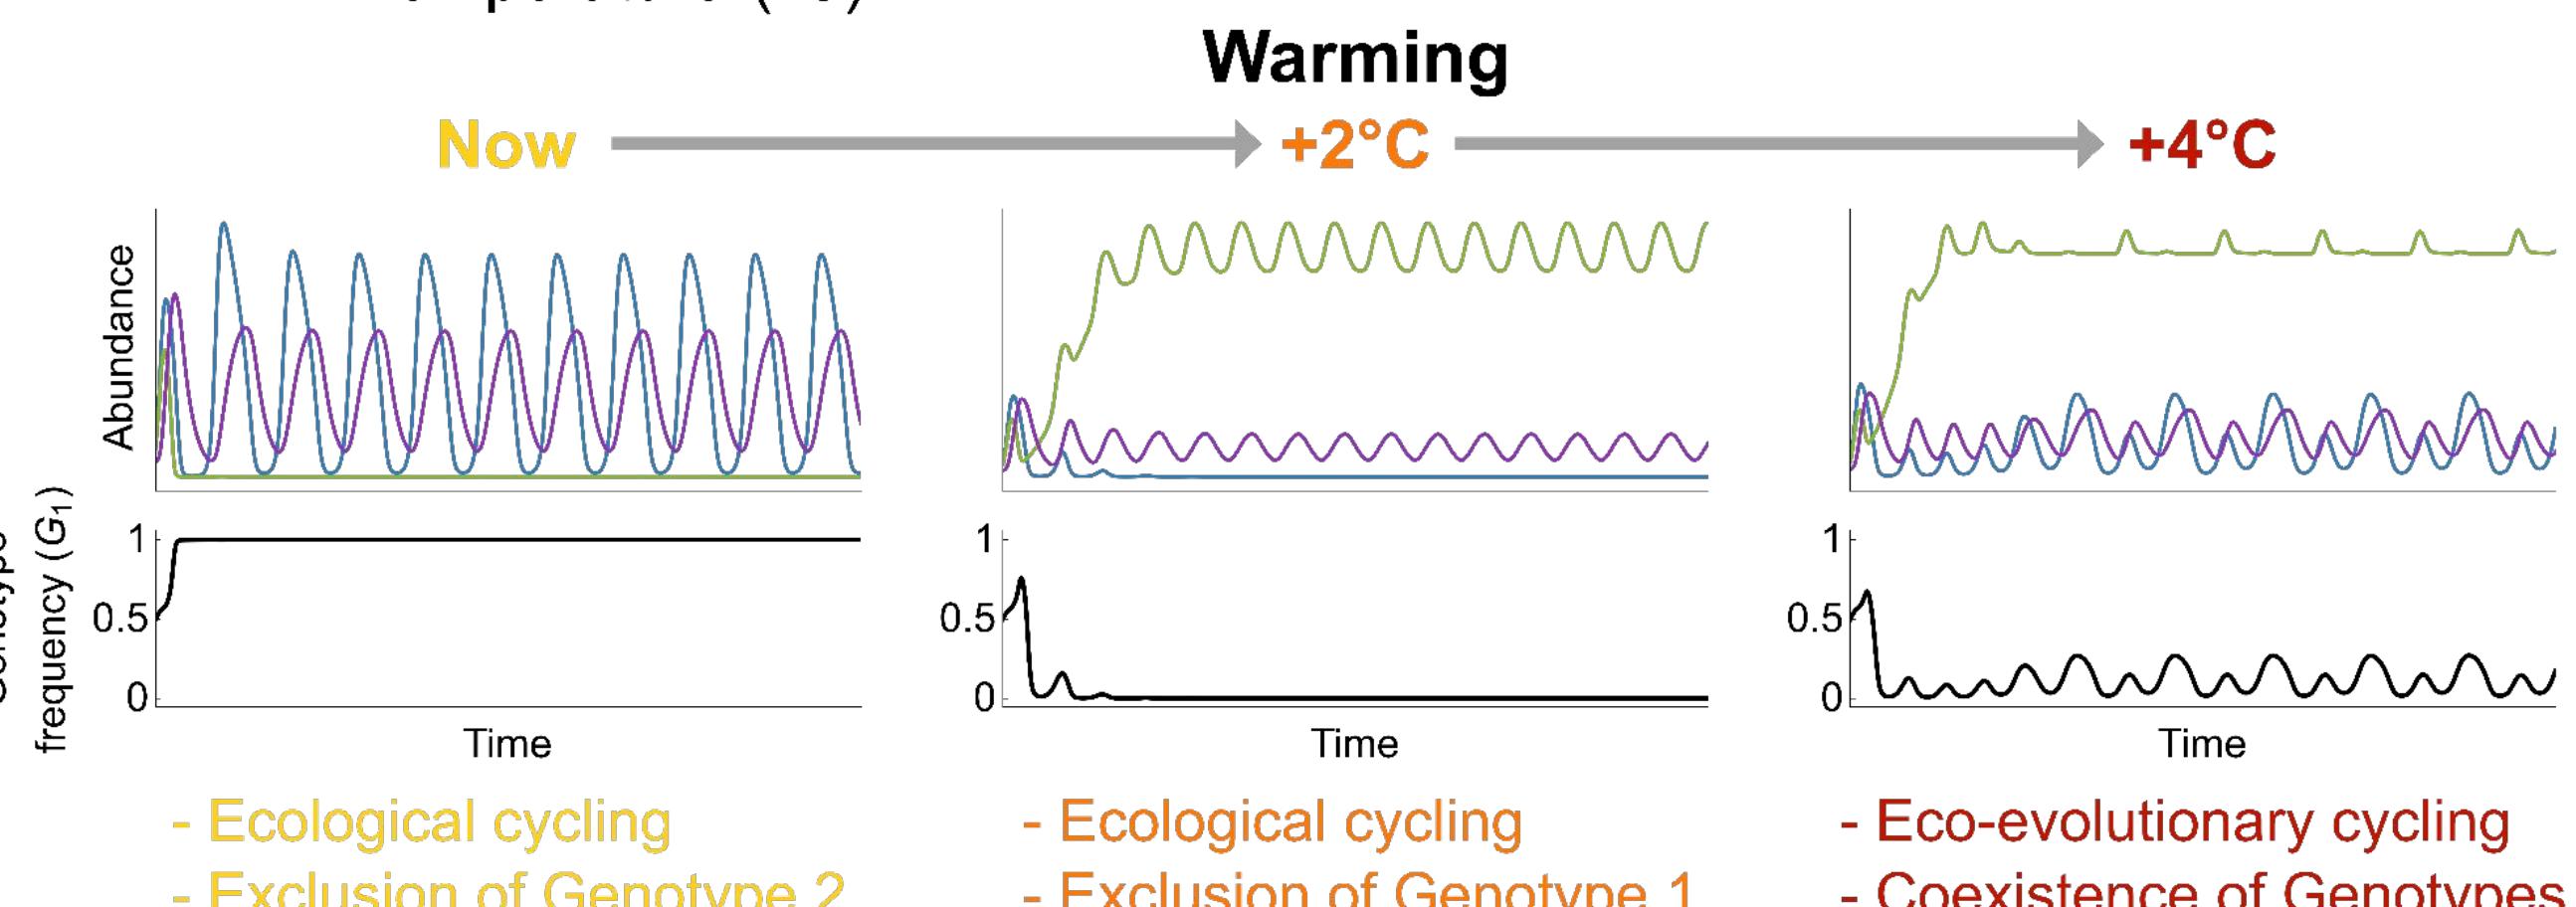

$$\text{Predator: } \frac{dP}{dt} = \varepsilon P \sum_{i=1}^2 f_i(G_i) - mP$$

$$\text{Prey: } \frac{dG_i}{dt} = r_i G_i \left(1 - \frac{G_i}{K_i}\right) - f_i(G_i) G_i P$$

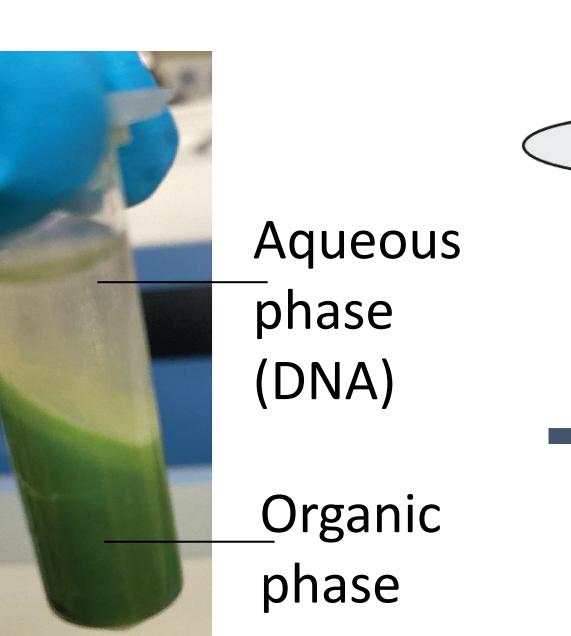

- Results**
- 1) Warming creates eco-evolutionary transitions
  - 2) Warming alters genotypic diversity

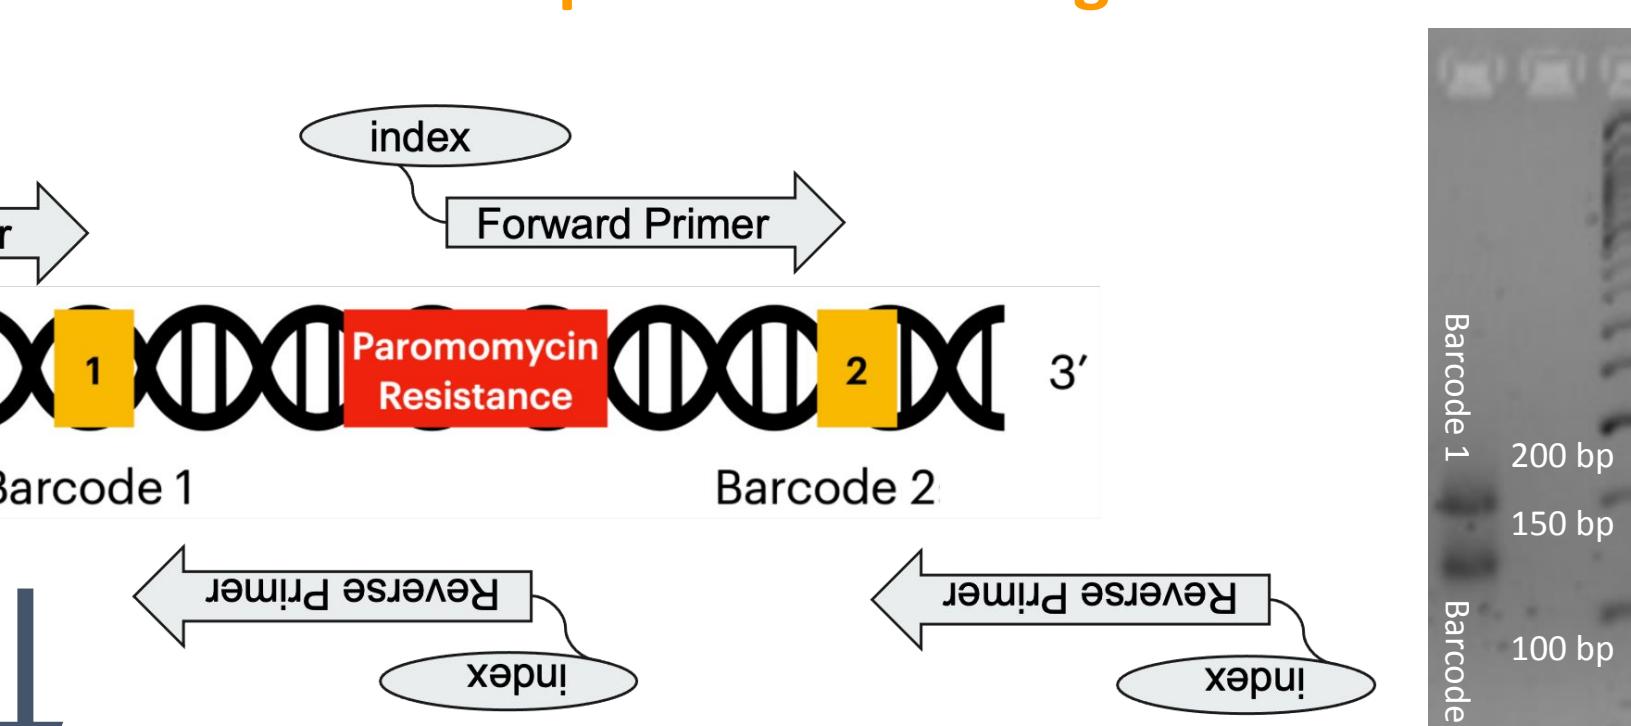

## Quantifying Evolution

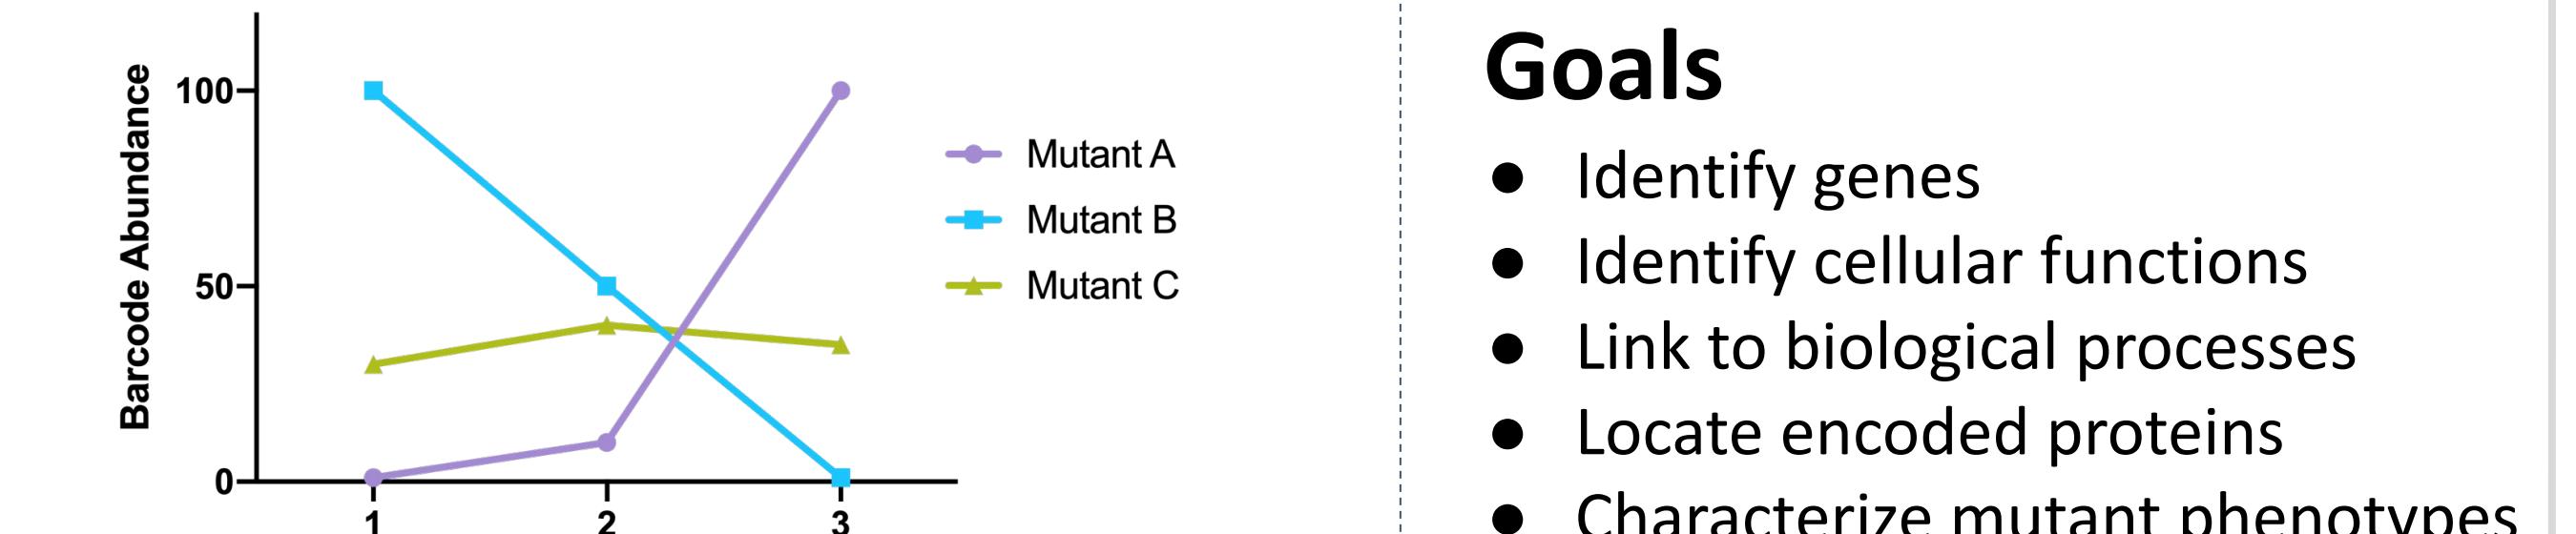

### 1. DNA Extraction

### 2. Barcode amplification through PCR

### 3. Amplicon sequencing to quantify evolution

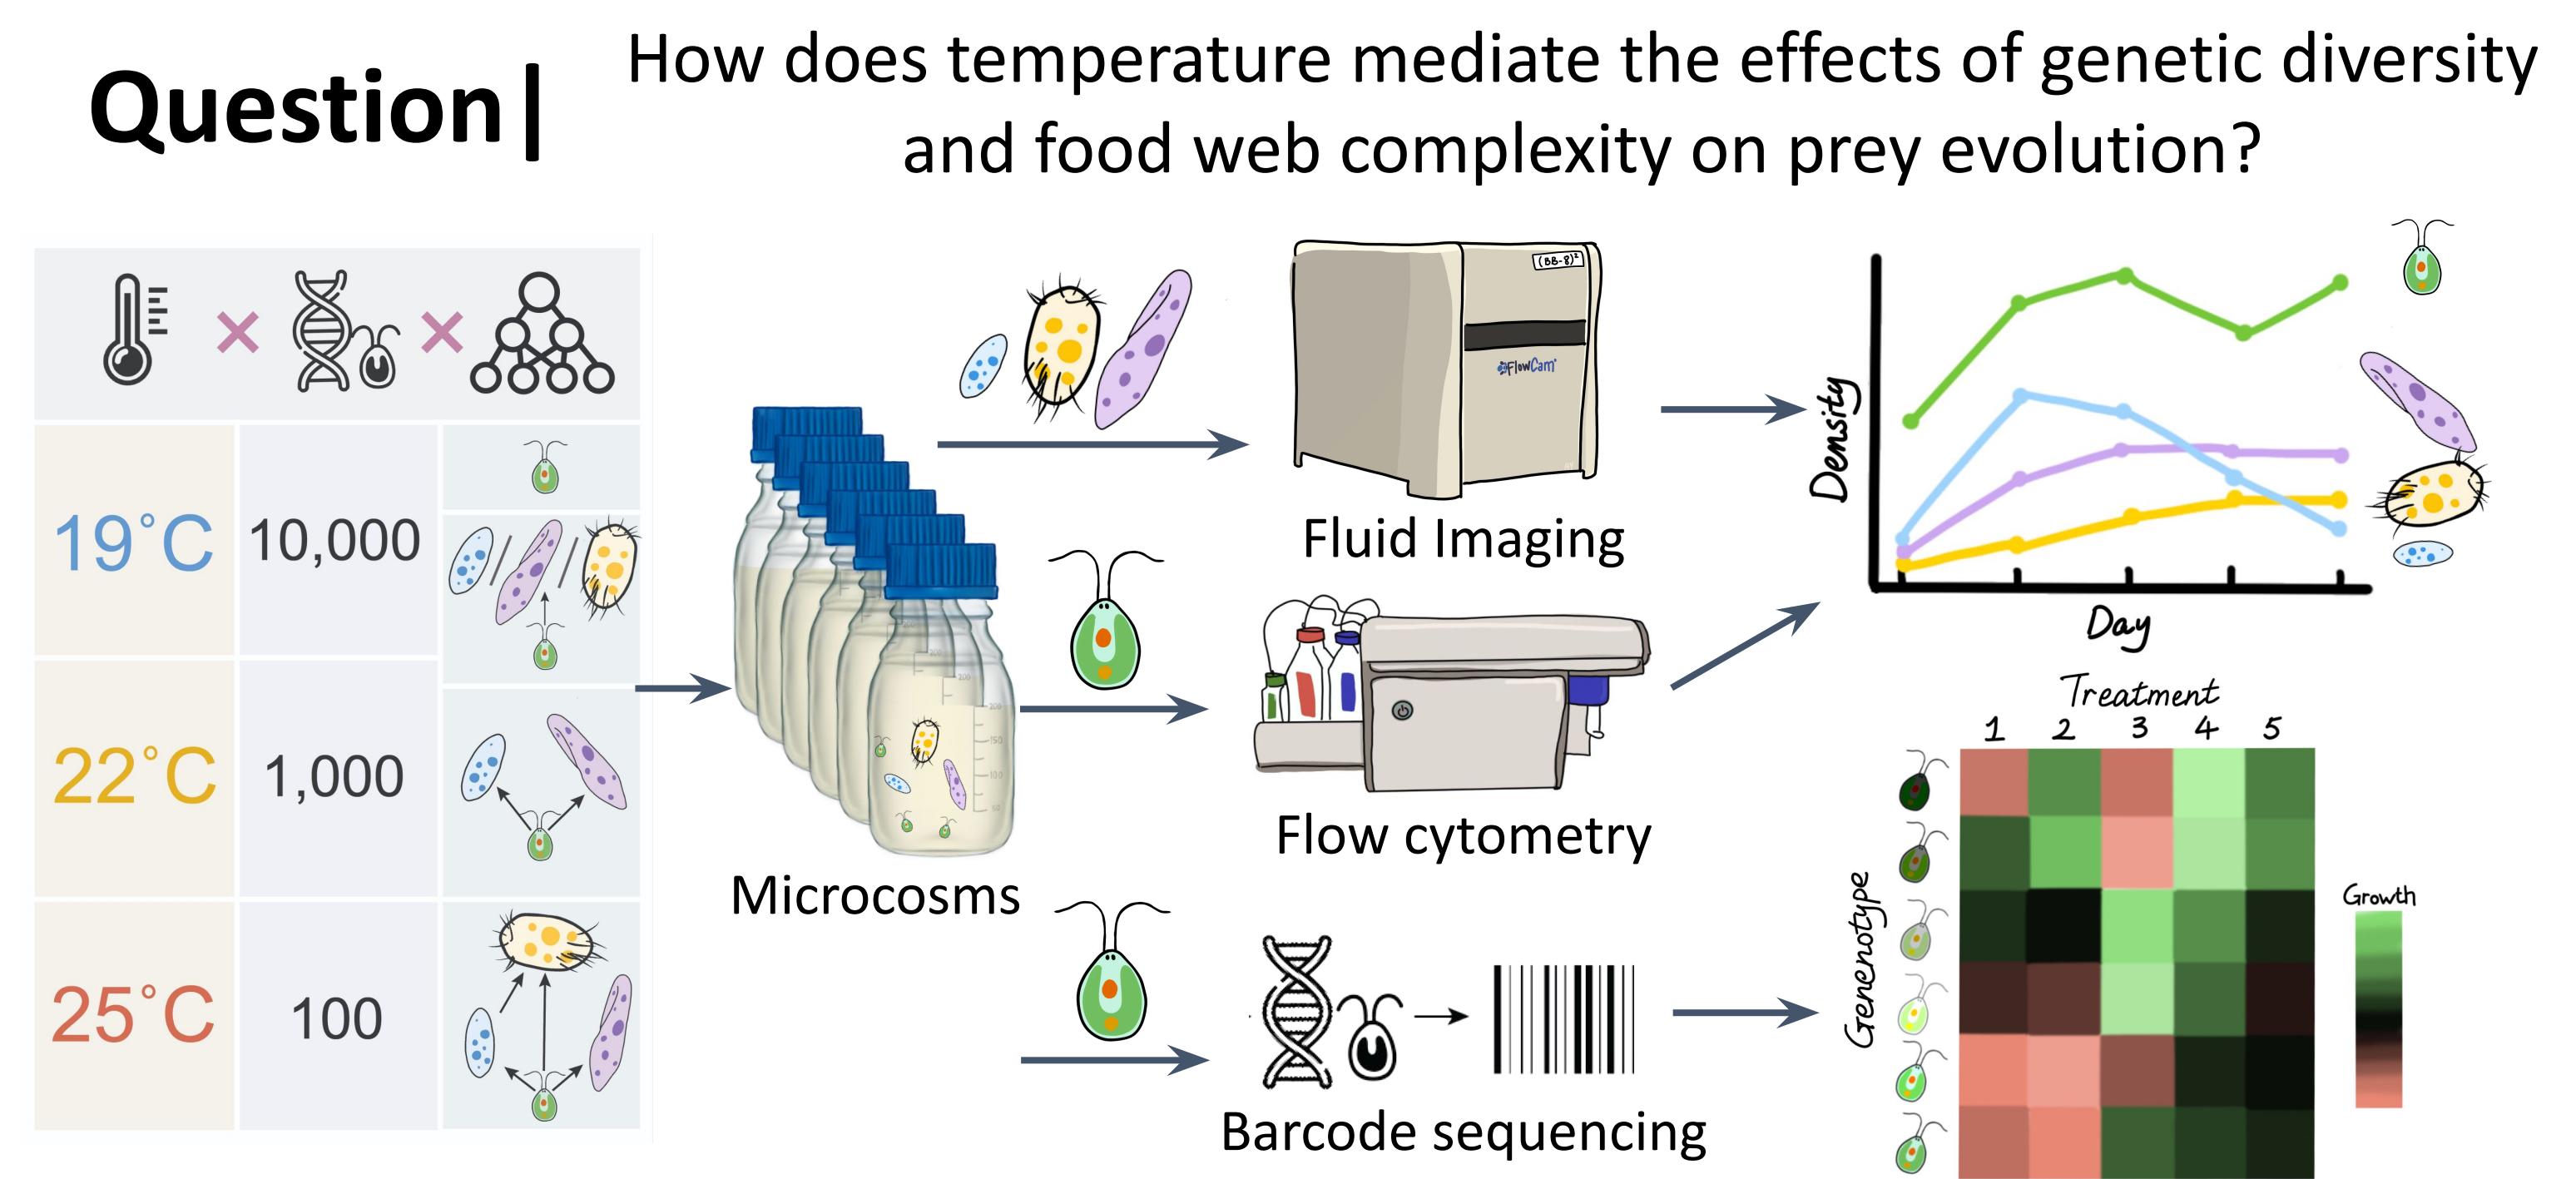

### Goals

- Identify genes
- Identify cellular functions
- Link to biological processes
- Locate encoded proteins
- Characterize mutant phenotypes

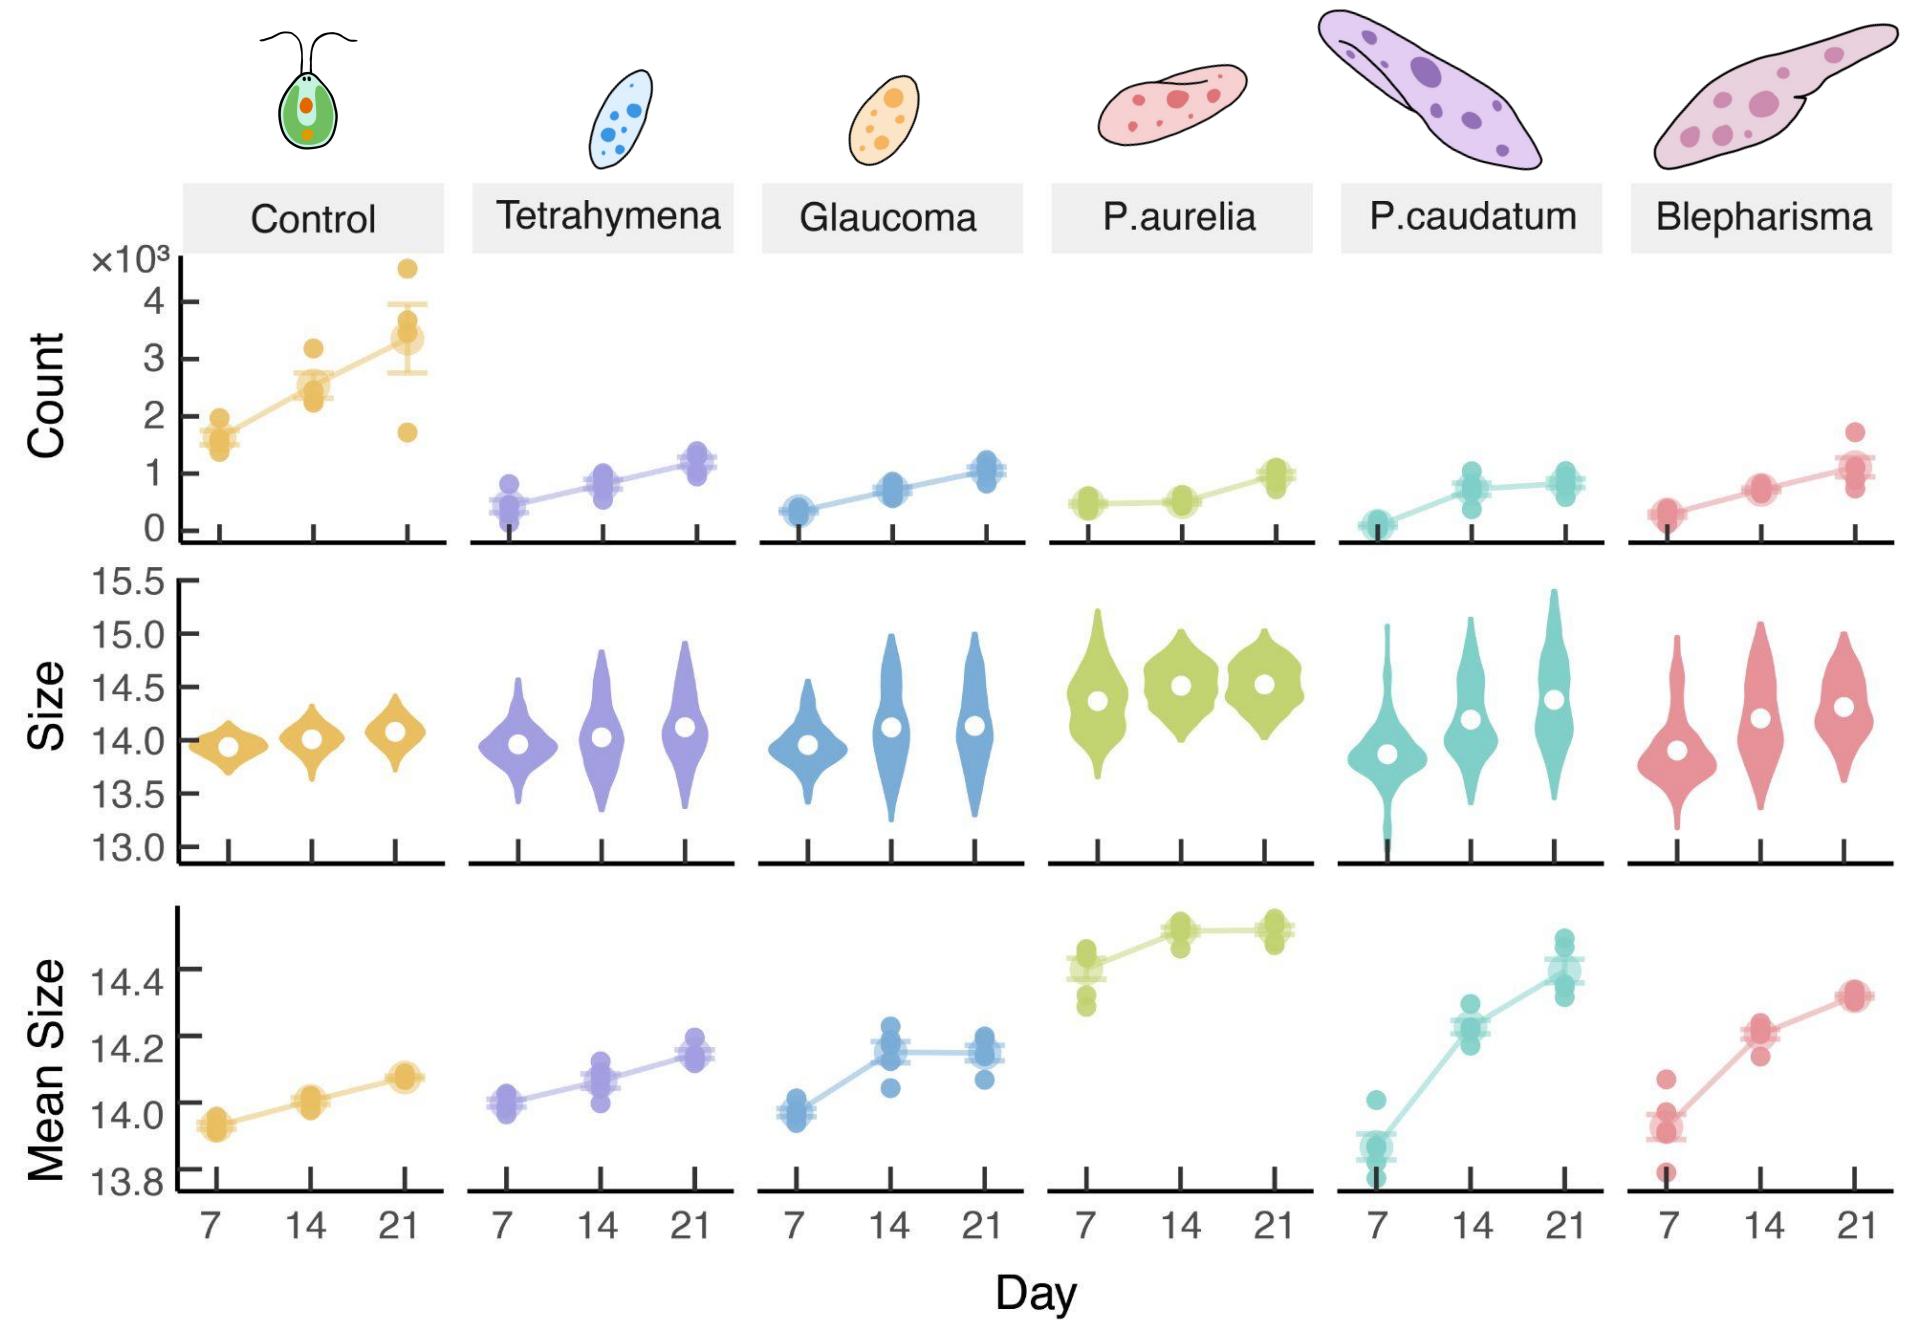

## Eco-Evo Experiment

### Question |

## Preliminary Results

### Experiment I

*Predators have different effects on prey densities and phenotypes*

- Predators eat *C.reinhardtii* at different rates
- Predators induce different plastic defensive responses

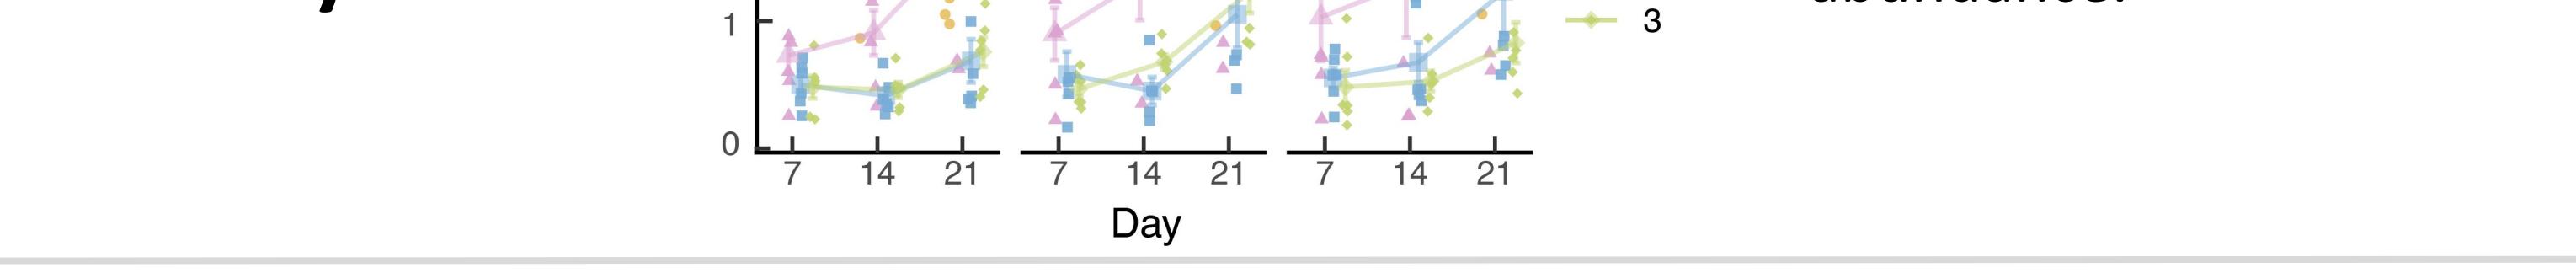

### Experiment II

*Predator diversity (PD) and standing genetic variation (GV) interact to affect selection on prey*

### Microcosm Experimental Design

GV	PD	Control	1 predator	2 predators	3 predators
1000					
100					
10					

### Ecological Dynamics

*Genetic diversity increases *C. reinhardtii* population abundance.*

**Next steps |** 1) Quantify genetic variation    2) Map genotypes to phenotypes
